

AI ASSISTED CODING

NAME: G.SANJANA

ENROLL NUMBER: 2403A52380

BATCH NUMBER :14

Lab assignment-10.4

Task 1: Syntax and Error Detection

Task: Identify and fix syntax, indentation, and variable errors in the given script.

```
# buggy_code_task1.py

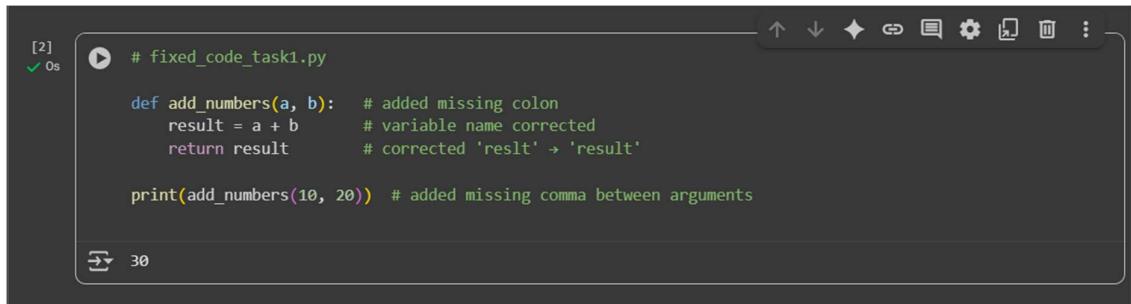

def add_numbers(a, b)

    result = a + b

    return reslt

print(add_numbers(10 20))
```

code:

A screenshot of a terminal window titled '# fixed_code_task1.py'. The code contains three lines of Python: a function definition 'def add_numbers(a, b):' with a missing colon, a corrected variable name 'result', and a corrected argument name 'reslt'. A note indicates the correction of 'reslt' to 'result'. Below the function is a call to 'print(add_numbers(10, 20))' with a missing comma between the arguments. The terminal shows the output '30'.

```
[2] ✓ 0s # fixed_code_task1.py
def add_numbers(a, b):    # added missing colon
    result = a + b        # variable name corrected
    return result          # corrected 'reslt' → 'result'

print(add_numbers(10, 20)) # added missing comma between arguments
30
```

Fixes made:

- Added : after def add_numbers(a, b)
- Corrected variable typo reslt → result
- Added missing comma in
print(add_numbers(10, 20))

Task 2: Logical and Performance Issue Review

Task: Optimize inefficient logic while keeping the result correct.

```
# buggy_code_task2.py
def find_duplicates(nums):
    duplicates = []
    for i in range(len(nums)):
        for j in range(len(nums)):
            if i != j and nums[i] == nums[j] and nums[i] not in duplicates:
```

```

        duplicates.append(nums[i])

    return duplicates

numbers = [1,2,3,2,4,5,1,6,1,2]

print(find_duplicates(numbers))

```

code:

The screenshot shows a code editor window with the following Python code:

```

# fixed_code_task2.py

def find_duplicates(nums):
    seen = set()
    duplicates = set()

    for num in nums:
        if num in seen:
            duplicates.add(num)
        else:
            seen.add(num)

    return list(duplicates)

numbers = [1, 2, 3, 2, 4, 5, 1, 6, 1, 2]
print(find_duplicates(numbers))

```

The output of the code is displayed at the bottom of the editor window: [1, 2].

Optimizations:

- Replaced nested loops with **single loop**.
- Used **set membership ($O(1)$)** instead of repeated list lookups ($O(n)$).
- Collect duplicates in a **set** (avoids duplicates automatically).
- Converted result back to a list at the end.

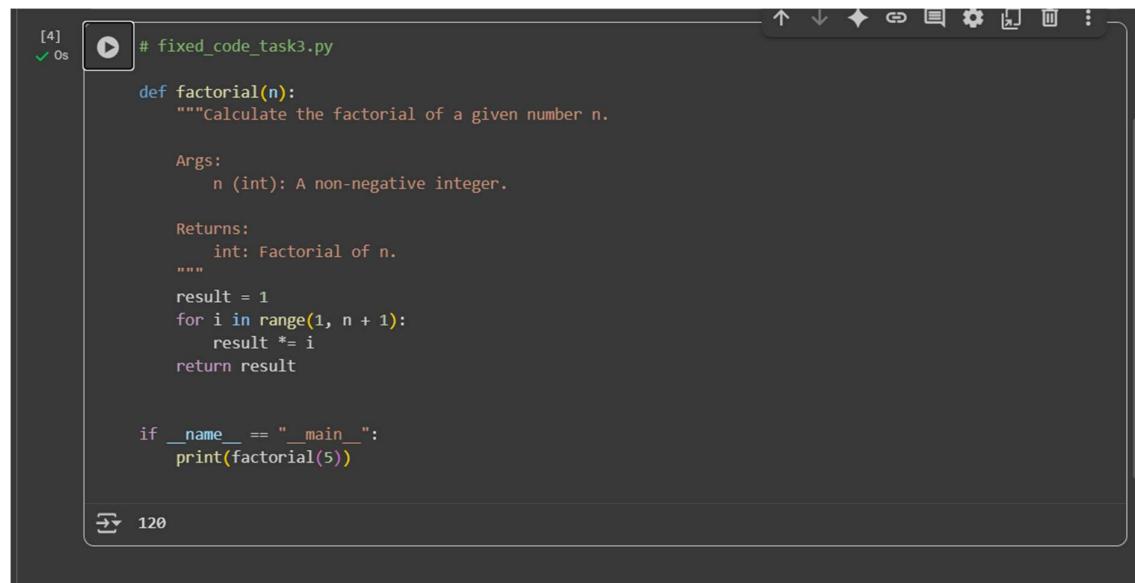

Task 3: Code Refactoring for Readability

Task: Refactor messy code into clean, PEP 8-compliant, well-structured code.

```
# buggy_code_task3.py
```

```
def c(n):
    x=1
    for i in range(1,n+1):
        x=x*i
    return x
print(c(5))
```

code:

The screenshot shows a code editor window with the following content:

```
[4] ✓ 0s # fixed_code_task3.py
def factorial(n):
    """calculate the factorial of a given number n.

    Args:
        n (int): A non-negative integer.

    Returns:
        int: Factorial of n.
    """
    result = 1
    for i in range(1, n + 1):
        result *= i
    return result

if __name__ == "__main__":
    print(factorial(5))

→ 120
```

The code has been refactored into a clean function named `factorial` with a docstring. The original code is shown in a light gray background, indicating it is no longer the active version.

Refactoring improvements:

- Renamed function c → factorial (clearer).
- Renamed variable x → result.
- Added **docstring** (PEP 257).
- Fixed indentation (4 spaces).
- Wrapped print in if __name__ == "__main__": → better structure for reusability.

Task 4: Security and Error Handling Enhancement

Task: Add security practices and exception handling to the code.

```
# buggy_code_task4.py

import sqlite3

def get_user_data(user_id):

    conn = sqlite3.connect("users.db")

    cursor = conn.cursor()

    query = f"SELECT * FROM users WHERE id = {user_id};" # Potential
    SQL injection risk

    cursor.execute(query)
```

```
result = cursor.fetchall()

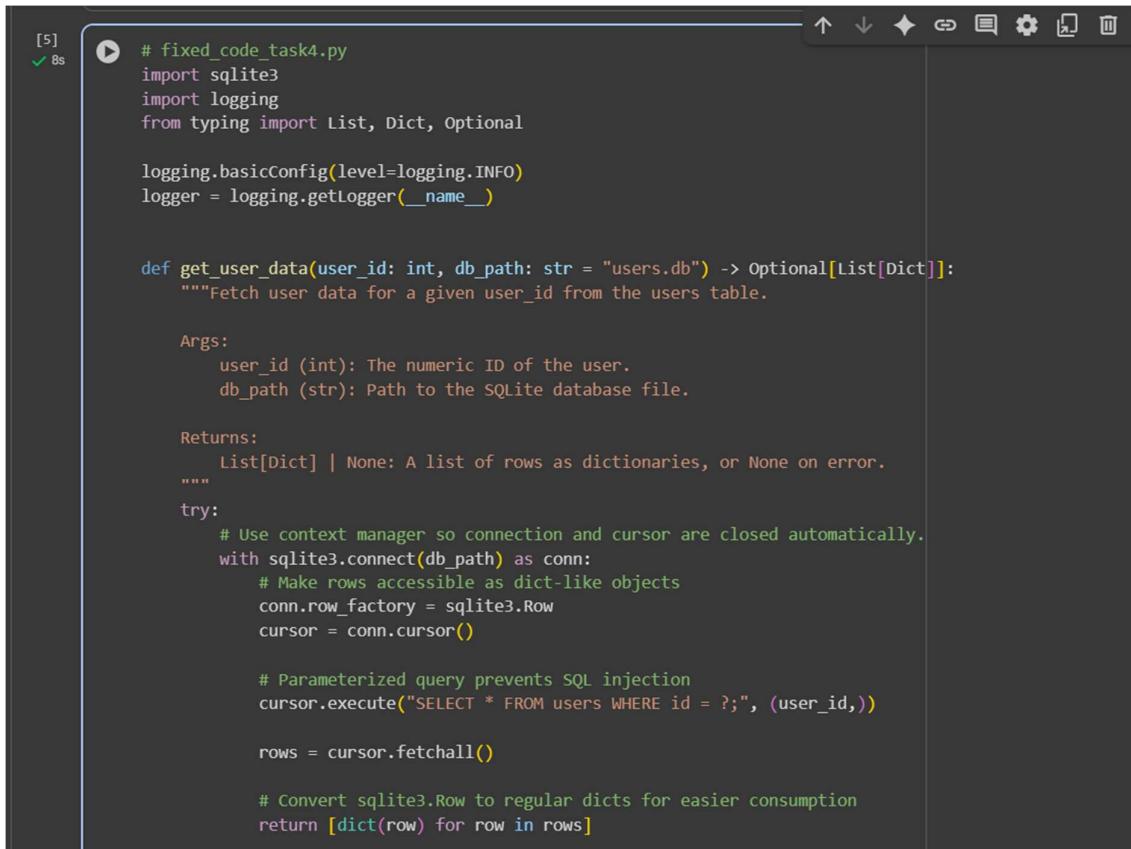

conn.close()

return result

user_input = input("Enter user ID: ")

print(get_user_data(user_input))
```

code:

The screenshot shows a code editor window with a dark theme. The file being edited is named `fixed_code_task4.py`. The code implements a function `get_user_data` that retrieves user data from a SQLite database. The code includes documentation strings for the function and its parameters, as well as detailed comments explaining the logic. The code editor has a status bar at the top indicating [5] and 8s.

```
[5]
8s
# fixed_code_task4.py
import sqlite3
import logging
from typing import List, Dict, Optional

logging.basicConfig(level=logging.INFO)
logger = logging.getLogger(__name__)

def get_user_data(user_id: int, db_path: str = "users.db") -> Optional[List[Dict]]:
    """Fetch user data for a given user_id from the users table.

    Args:
        user_id (int): The numeric ID of the user.
        db_path (str): Path to the SQLite database file.

    Returns:
        List[Dict] | None: A list of rows as dictionaries, or None on error.
    """
    try:
        # Use context manager so connection and cursor are closed automatically.
        with sqlite3.connect(db_path) as conn:
            # Make rows accessible as dict-like objects
            conn.row_factory = sqlite3.Row
            cursor = conn.cursor()

            # Parameterized query prevents SQL injection
            cursor.execute("SELECT * FROM users WHERE id = ?", (user_id,))

            rows = cursor.fetchall()

            # Convert sqlite3.Row to regular dicts for easier consumption
            return [dict(row) for row in rows]
    except Exception as e:
        logger.error(f"An error occurred while fetching user data: {e}")
        return None
```

```
    except sqlite3.Error as e:
        # Log the error for diagnostics; do not expose DB internals to users
        logger.exception("Database error while fetching user data.")
        return None

def prompt_user_id() -> Optional[int]:
    """Prompt user for an integer user ID and return it or None on invalid input."""
    raw = input("Enter user ID: ").strip()
    if not raw:
        logger.info("No input provided.")
        return None

    try:
        uid = int(raw)
        if uid < 0:
            logger.info("User ID must be non-negative.")
            return None
        return uid
    except ValueError:
        logger.info("Invalid user ID. Please enter a numeric value.")
        return None

def main():
    user_id = prompt_user_id()
    if user_id is None:
        print("Invalid input. Exiting.")
        return

    result = get_user_data(user_id)
    if result is None:
        print("An error occurred while fetching user data. Please try again later.")
    elif not result:
        print("No user found with the specified ID.")
```

```
[5] 8s  ▶ result = get_user_data(user_id)
if result is None:
    print("An error occurred while fetching user data. Please try again later.")
elif not result:
    print("No user found with the specified ID.")
else:
    # Pretty-print the returned records
    for record in result:
        print(record)

if __name__ == "__main__":
    main()

Enter user ID: 2402
ERROR: __main__:Database error while fetching user data.
Traceback (most recent call last):
  File "/tmp/ipython-input-4041158386.py", line 28, in get_user_data
    cursor.execute("SELECT * FROM users WHERE id = ?;", (user_id,))
sqlite3.OperationalError: no such table: users
An error occurred while fetching user data. Please try again later.
```

Code explanation:

- ❑ Uses **parameterized queries** (prevents SQL injection).
- ❑ Validates and converts the user_id input to an int.
- ❑ Uses **context managers** (with) to ensure DB resources are closed.
- ❑ Sets row_factory to sqlite3.Row and returns rows as dictionaries.
- ❑ Adds **exception handling** for ValueError and sqlite3.Error.
- ❑ Uses logging instead of printing raw exceptions (safer for production).
- ❑ Avoids exposing internal error details to the end user

Notes & further improvements

- If you expect multiple ways to identify a user (username, email), add separate, strongly validated paths rather than interpolating them into SQL.
- For production systems consider:
 - Storing DB credentials/config separately (not hardcoded).
 - Using an application-level ORM (e.g., SQLAlchemy) for more complex DB logic and safety.
 - More granular logging levels and possibly masking sensitive fields before logging.
- If users.db or the users table doesn't exist yet, this code will handle the error gracefully and log the exception.

Task: Generate a review report for this messy code.

```
# buggy_code_task5.py
```

```
def calc(x,y,z):  
    if z=="add":  
        return x+y  
    elif z=="sub": return x-y  
    elif z=="mul":  
        return x*y  
    elif z=="div":  
        return x/y  
    else: print("wrong")
```

```
print(calc(10,5,"add"))  
print(calc(10,0,"div"))
```

code:

```
[7] ✓ 0s # fixed_code_task5.py

def calculate(a: float, b: float, operation: str) -> float:

    operations = {
        "add": lambda x, y: x + y,
        "sub": lambda x, y: x - y,
        "mul": lambda x, y: x * y,
        "div": lambda x, y: x / y if y != 0 else (_ for _ in ()).throw(ZeroDivisionError("Division by zero"))
    }

    if operation not in operations:
        raise ValueError(f"Invalid operation: {operation}")

    return operations[operation](a, b)

if __name__ == "__main__":
    print(calculate(10, 5, "add"))
    try:
        print(calculate(10, 0, "div"))
    except ZeroDivisionError as e:
        print(f"Error: {e}")

→ 15
Error: Division by zero
```

Code Review Report

File: buggy_code_task5.py

✓ Strengths

- Functionality covered:** Supports four basic arithmetic operations (add, subtract, multiply, divide).
 - Simple and direct structure:** Easy to follow for small use cases.
-

⚠️ Issues Identified

1. PEP 8 Non-Compliance

- Indentation inconsistent (if and elif blocks should be indented 4 spaces).
- Inline statement elif z=="sub": return x-y breaks readability.
- Function and variable names (calc, x, y, z) are not descriptive.

2. Error Handling

- Division by zero is not handled → causes ZeroDivisionError.
- Invalid operation (else) prints "wrong" but does not return a proper value (returns None).

3. Readability & Maintainability

- No **docstring** explaining the function's purpose, arguments, or return type.
- Operation names ("add", "sub", etc.) are magic strings → prone to typos.
- Mixing of print and return inside the function → inconsistent interface.

4. Scalability

- Every new operation requires another elif.
- Better design would use a **dictionary dispatch pattern** for cleaner extensibility
